

Website Migration: Automated Link Replacement Guide

This workflow automates the identification, downloading, and re-linking of files during website migration.

Part 1: Link Analyzer Bookmarklet

Goal: Instantly identify and color-code all links on a page to distinguish between subpages, external links, and downloadable files.

Setup

1. Show Bookmarks Bar: Press Ctrl + Shift + B (Windows) or Cmd + Shift + B (Mac).
2. Add Bookmark: Right-click any empty space on the bookmarks bar and select "Add Page".
3. Configure:
 - o Set the Name to something like "Analyze Links".
 - o In the URL field, copy and paste the following JavaScript code
 - o Replace 'xxx' in var k=['xxx']; with your target domain keyword (e.g., 'example.edu')

```
javascript:(function(){var k=['xxx'];var
f=/\. (pdf|docx?|xlsx?|pptx?|zip|rar|tar|gz|tex|ps|txt|jpg|png|gif|c|cpp|h|hpp|py|java|
m|sh|dat|mp4|mp3|mov|avi)(?:[\/?#].*)?$\/i;var
a=document.querySelectorAll('a[href]');var
eu=[],pu=[],fiu=[];a.forEach(function(l){if(!l.href.startsWith('http'))return;var
h=l.href.toLowerCase();var isIn=k.some(function(kw){return
h.includes(kw.toLowerCase())});var
isFile=f.test(h);if(!isIn){eu.push(l.href);l.style.backgroundColor='#ffc107';l.style.b
order='2px dashed
#ffc107';l.style.color='#000'}else{if(isFile){fiu.push(l.href);l.style.backgroundColor
='#c8e6c9';l.style.border='2px solid
#388e3c';l.style.color='#000'}else{pu.push(l.href);l.style.backgroundColor='#81d4fa';l
.style.border='2px solid #0288d1';l.style.color='#000'}}});var txt===" External Links
===\n"+[...new Set(eu)].join('\n')+"\n\n=== Internal Files ===\n"+[...new
Set(fiu)].join('\n')+"\n\n=== Internal Webpages ===\n"+[...new
Set(pu)].join('\n');navigator.clipboard.writeText(txt);})();
```

4. Click the bookmark on your target page. Links will change color immediately:

- **Blue** means it's an internal subpage we need to rebuild.
- **Yellow** is an external link, which we don't need to worry about.
- **Green** means it's a file.

Notes:

1. A single site may span multiple domains. In that case, add all relevant domain keywords into the script's **k** array, and do a manual review afterward.
2. URLs without a file extension will be flagged as Blue (subpage) even if they point to a file, so a manual check is recommended.

Part 2: Bulk Downloading with DownThemAll!

Goal: Post-migration, any linked PDFs, documents, etc., will need to be hosted in Google Drive and linked from there. To avoid manually clicking each file, we use the "DownThemAll!" Chrome extension to bulk download them at once.

Chrome Preparation

Before using the extension, ensure Chrome doesn't interrupt your bulk download with pop-ups:

1. Go to Chrome **Settings** -> **Downloads**.
2. Set your default download **Location**.
 - If you install Google Drive for Desktop, you can set this download location directly to the mapped Google Drive folder on your PC (e.g., your G: drive). The downloaded files will automatically sync to the cloud!
3. **Turn OFF** the option: "Ask where to save each file before downloading".

Downloading Steps

1. On the target page (where you just ran the Analyzer Bookmarklet), click the **DownThemAll!** extension icon in your browser toolbar.
2. At the bottom of the pop-up window, locate the "**Fast Filtering**" search box. Enter your target domain path (e.g., **files.example.edu**) so the list excludes external links.
3. Check the "**Disable others**" box.
4. Review the remaining list and manually **uncheck any .html files** (we only want actual documents, not webpages).
5. Under the **Filters** section, ensure only "**All files**" is selected. Click the Download button.

Tracking the Download

6. Click the DownThemAll! extension icon again and select **Manager** to open the active download queue.

Notes:

- **Foreground Requirement:** You must keep the DownThemAll! Manager tab actively open in the foreground until all downloads finish. Due to a known Chrome conflict, letting it run in the background may cause every file to download twice.
- **Next Steps:** Once all files are successfully downloaded to your local drive, upload the entire batch to your designated Google Drive folder.

Part 3: Automated Link Replacement (Google Apps Script)

Goal: Now that all the files are safely hosted in Google Drive, the final step is to automatically swap the old URLs in the text with the new Google Drive links.

Crucial Limitation: Unique Filenames Required

This script matches files based on their names. It works best when files have distinct names. If a page has multiple different files sharing the exact same name (e.g., several syllabus.pdf files from different folders), this automation will not work. The script will highlight all such links in Orange, make zero replacements, and you will have to link them all manually.

Document Preparation

1. Copy all the content from the old webpage and paste it into a blank **Google Doc**.
2. Select everything (Ctrl + A), then press Ctrl + \. This clears messy HTML formatting while preserving the basic document structure.
3. Click **Extensions -> Apps Script** from the top menu.
4. Delete any default code and paste in the script from [apps-script/replace-links.gs](#) in this repository.

Execution & Review

1. Click **Save project** (the disk icon), then click **Run**. (The first time you run this script, Google will ask for permission to access your Docs and Drive. Click Allow.)
2. Review the **Execution Log** at the bottom of the screen to see how many links succeeded, failed, or conflicted.
3. Go back to your Google Doc. The modified areas will be highlighted:
 - **Green:** The link was successfully replaced with the Drive URL.
 - **Red:** It failed—usually because it's a subpage or the file wasn't downloaded.
 - **Orange:** Conflict. There are two or more files with the exact same name in your Drive. **The script will NOT replace these links.** You must manually review and fix them. Please check the **Execution Log**—it will output the original URLs of these problematic files to help you locate them.

Finalizing in Google Sites

1. Copy the fully processed text from your Google Doc and paste it into a Google Sites text box.
2. Select all (Ctrl + A), then press Ctrl + \ again. This allows Google Sites to automatically adjust the text to match its built-in theme.

Note: Clearing formatting will also remove **bold** and *italic styles*. You will need to re-apply these manually.
